Foreword

I never thought that I would write a book about Smart Money Concept trading. But, the more I teach people how to trade Forex, the more educational articles, signals, analytics, live streams and videos I provide, the more I realize that people completely does not understand what is SMC about.

I became an authoritative trading mentor on TradingView, Telegram and YouTube, showing a real face of Forex trading.

In contrast to "gurus" out there, stating how easy trading is, showing fake luxury lifestyle of traders, posting unrealistic profits and making unenforceable promises to their students, I am always trying to show how complicated and risky trading really is, and how to trade the financial markets properly.

With a growing popularity of Smart Money Concept, more and more fake traders started to spoil this niche.

More and more I started to see SMC ads like "trade with hedge funds", "think like a banker"...

Since 2020, I constantly hear statements like: "classic technical analysis does not work anymore", "if you want to make real money, you should learn smart money trading", "the only strategy that works is SMC".

My goal is to show you a true nature of Smart Money Concept, help you to build realistic expectations with trading that strategy and explain why classic technical analysis is even more powerful than it seems.

Introduction

Smart Money Concept is one of the most vague techniques in Forex trading. If you search a book about SMC on Amazon, you will quickly realize that there is no single book that would explain what is Smart Money Concept and teach how to trade it. I am not trying to say that the entire search result will be empty. In contrast, there will be a lot of materials to read. But all the papers that you will find are poorly written and terribly structured. The authors are no names, without any proof of experience and authority in the field.

If you decide to read different articles on Google about Smart Money Concepts, again, you will quickly come to the conclusion that 90% of the articles are a complete nonsense. With doctored trading examples with unrealistic gains.

The only available way for the newbie traders to study Smart Money Concept nowadays is YouTube. There are a lot of videos from different traders on that subject. The main problem is, however, that all these videos are not structured in one learning series. Video makers jump from one topic to another, using complicated terminology and slang that a beginner can not understand.

With that book, my goal is to explain to you what is Smart Money Concept, how it emerged, what are the principles it is based on and how to trade it. We will go through the origins of SMC and its terminology. I will show you how I apply that in trading different financial markets and share with you my full trading strategy.

I promise that after completing this book, you will be able to act and think like a Smart Money Trader. I strongly believe that it will be the only book you need to master SMC.

Take notes and let's get started!

Forex Market Participants & Smart Money

In order to understand the logic of Smart Money Concept trading, we will start with discussing Forex Market Participants.

Forex market is huge and unites different players of different size and shape. Here is the list of the main categories of the market participants you should know about:

1. Central Banks

Central banks play a crucial role in Forex market. They set monetary policy, manage and control home currency of the country. Central banks may intervene on the market to achieve a particular economic goal.

The examples of big central banks are Federal Reserve in the US (FED), European Central Bank in EU (ECB), Bank of Japan in Japan (BOJ).

2. Commercial Banks

The activity of commercial banks constitutes the largest daily trading volumes on Forex market. Commercial banks engage on the market in several ways: they provide currency transactions for its clients and hedging services for management of currency fluctuation risks. Commercial banks can also be involved in currency speculations.

3. Institutional Investors

By the institutional investors I mean hedge funds, mutual funds, pension funds, etc. These large financial institutions have diverse financial objectives on Forex market such as portfolio management, diversification, hedging and investing.

4. Retail Traders

Retail traders are the individuals that are involved in trading and speculation on Forex market. Such traders are aimed to benefit from currencies price movements. Usually, for the execution of their trading positions, they use the services of brokers.

5. Market Makers

Market maker is the financial institution that provides a liquidity to a Forex market, providing bid and ask prices for FX pairs. It ensures the stability of the market and a smooth flow of orders and transactions. Market maker makes money on currencies spread and speculations.

Different categories of the Forex market participants have own intentions. Their goals define their actions.

While the main goal of retail traders is to benefit from short term, long term and mid term market movements, bigger players may exploit the market in completely different ways.

There are **2 crucial things** that unites all big players and distinguishes them from retail traders.

1. Big players operate on the market with large trading volumes. Hence, they constantly need liquidity.

For that reason, their activity is aimed at the accumulation of the liquidity and grabbing that from the market.

2. Big players have the access to insider or any other kind of information that provides a tangible advantage in predicting the market behavior. They have significant resources and experience for market analysis and research.

Because of these particularities, big players are called Smart Money. Their deep understanding of the market dynamics, and their significant buying and selling activities, make them constantly one step ahead of the retail traders.

Quite often, the retail traders become the main aim of the Smart Money. With different types of market manipulations, they trick retail traders, inducing them to make wrong decisions.

Your ability to recognize these manipulations, exploit it, understand and predict the actions of big players is the core of Smart Money Concept trading.

Market Inefficiency

If Smart Money are constantly ahead of us - the retail traders and if we are constantly targeted by their manipulations, the question arises:

is it still possible to make money in Forex trading?

There is one thing that Smart Money are not able to fully control - **the market inefficiency**.

What is Efficient Market?

In order to understand the concept of market inefficiency, first, let's discuss what is the **market efficiency**.

The price of an asset is constantly striving to find a fair value.

A fair value is the price of an asset that provides the **equilibrium** between supply and demand on the market.

A fair value is weighted by the perception of the market participants based on all the news and data that is available about the asset. Simply put, that is the price that all the market participants **agree about**.

On the price chart, a fair value of an asset usually represents a price range. A horizontal parallel channel on a price chart where the price stuck and remains stable for a relatively long period of time.

Look at EURUSD on a daily time frame. After quite an extended bearish movement, the market stopped falling and started to trade within a horizontal range. The pair found a fair value.

According to the theory, the efficient market reflects all the information that is available about the asset in its price. Hence, in the efficient market, the price equals or almost equals the fair value.

Please, note that **100% efficient markets do not exist**. It is the economic utopia. But the nature of the financial markets continuously aims to maximize its efficiency levels.

What is Market Inefficiency?

However, the surprising fundamental data, news, and rumors make the market **reassess** the fair value, creating an **imbalance in supply and demand** and making the price shift rapidly.

Such price adjustments are called the **market inefficiency**.

Common characteristics of the market inefficiency are **high momentum candles and price gaps**.

In technical analysis, the violation of one of the boundaries of the fair value horizontal ranges usually **confirm** the inefficiency.

Please, note that human factor also may cause the market inefficiency. The examples of such inefficiencies can be emotional decisions, wrong evaluation and assessment of a fair value.

After consolidating within a range for almost a month, EURUSD turned bullish with the release of surprisingly positive fundamental news, causing a violation of the resistance of the range and a rapid bullish movement - the inefficiency.

New Fair Value

As the market participants interpret new data, the price strives to find a new fair value.

Strongly negative news push the market lower till the **equilibrium** in supply and demand is established and a new fair value price is found.

Such a situation occurred on CADCHF pair. After a long consolidation within a horizontal range, where the market found a fair value, the price dropped. The violation of the support of the range and rapid bearish movement is the example of the inefficiency.

The market found equilibrium and a fair value much lower and started to consolidate again.

Alternatively, highly positive news make the price go higher, till buyers and sellers will find the consensus and a fair value, making the market stop.

Look at a price action on EURCAD on a daily. The market found a fair value and was stuck within a horizontal range for a month.

Best Change of Character Models

As I mentioned earlier, in some particular cases, CHoCH may also **confirm the initiation of a new trend**. The price action before the CHoCH should meet **specific criteria**.

Best CHoCH Model in Bullish Trend

In a bullish trend, the price should form of a **Lower High before the CHoCH**. In such a situation, the market will not only violate a current bullish trend with Change of Character but also **establish a new bearish trend**, because the conditions for that will be met as well.

Look how a bullish trend violation and a bearish reversal was confirmed on EURUSD with CHoCH.

Best CHoCH Model in Bearish Trend

In a bearish trend, the price should set a **Higher Low before a Change of Character**. In such a case, the market will violate a current bearish trend and start trading in **a new bullish trend**, because the conditions for a bullish trend will be met.

That is what happened on EURCHF.

With CHoCH, the pair violated a bearish trend and also confirmed a new bullish trend.

These rules, setups, and models will help you to have a deeper understanding of market price action. Always check the preceding price action before Change of Character to make more accurate predictions and forecasts.

Advanced Market Trend Analysis

As we discussed, the core element of structure mapping is the **impulse leg**.

According to the definition, it is a **strong, directional bullish or bearish movement**.

While bullish/bearish are completely objective terms, the word strong is very subjective.

With such a method of analysis a big question arises: **what is exactly is the impulse leg, how strong and long** it should be. Which price fluctuations can be a part of the impulse and which should be excluded?

Impulse Leg in SMC

Look at the example above. A price action on AUDCAD can be perceived as **one single bullish impulse** or a **combination of 3 bullish impulses and retracements** or a **combination of multiple impulses and retracements**.

Which way of analysis is **correct**?

The fact is that the price action analysis on **each chart is correct**. The only difference between them is the **perspective**.

The Perspective

From a **long-term perspective**, the **entire price movement** on the chart is a **one single impulse**.

From a **mid-term perspective**, it is the market that is trading in a **bullish trend in 3 bullish impulses**.

From a **short-term perspective**, it is the market that is trading in a **bullish trend** and started to **consolidate** and trade in **sideways** for some time, resuming the growth then.

Here is the rule:

With advanced SMC trend analysis, you should learn to perceive a price chart not only as a combination of impulse and retracement legs, but also as a combination of **long-term, mid-term and short-term trends and movements**.

Depending on your trading style, such a reasoning and view on the market can be applied on any time frame.

Examples

Look at AUDJPY pair on an hourly time frame.

From a long-term perspective, the pair is trading in a bearish trend.

Studying in details the last bullish impulse, we can perceive it as a minor bullish trend with its confirmed violation after a Change of Character.

Let's discuss **another example**.

EURNZD is trading in a clear long-term bullish trend on a daily.

Zooming in the chart, we can also analyze the last bullish impulse in a long-term bullish trend as a mid-term bullish trend.

At the same time, if we analyze the recent minor movements, we can spot a confirmed minor bearish trend on the pair.

How to Apply Advanced Trend Analysis in SMC?

Why do we need such an in-depth market trend analysis?

Always remember that a **global trend** is always born from a **minor trend**. Minor trend analysis will help you to identify **local reversal or trend following signals much earlier**.

Returning to our example, the fact that EURNZD started to trade in a **minor bearish trend**, being **globally bullish**, can be an important **warning sign** for us.

You can see that after some time the pair started to fall rapidly.

A minor bearish trend continued, a mid-term bullish trend was violated and a correction started in a global bullish trend.

Your ability to correctly analyze different market perspectives is essential for making accurate predictions.

The trend analysis rules and events that we discussed are more than enough for successful trading any time frame and any market.

Structure Mapping Example

Look at the example of a **complete structure mapping** on Gold chart.

With the identification of the legs of the move, highs and lows, BoS and ChoCh you can clearly understand what is happening with the market: you can identify the direction of the market, global, mid term and short term sentiment.

Gold was trading in a **bearish trend**.

Once the level of our **Initial Low** was tested, the market started a **correctional movement** and started to trade in a minor **bullish trend** with 2 consequent **Breaks of Structure**.

Once some significant resistance was reached, the market **reversed**. We saw a confirmed **CHoCH** and the market returned to a global **bearish trend**.

Market Liquidity

In this chapter, we will discuss one of the essential topics in Smart Money Concept trading - market liquidity.

We will cover:

1. Supply and Demand,
2. Fair Value,
3. Imbalance,
4. Liquidity Zones

What is Liquidity

First, let's start with a definition of liquidity.

When the asset can easily and quickly bought or sold on the market, not affecting its price, we call such a market - **liquid** or the market with a high liquidity.

In contrast, **low liquidity** will signify that the asset may not be traded rapidly **without significant price changes**.

It happens because for placing any trade, you need to always find a **counterpart**:
if you want to **sell**, you need someone that will **buy from you**;
and if you **buy**, you need someone who will be **willing to sell**.

High liquidity represents a situation when there is a **constant flow of buying and selling orders**, so that **supply and demand remain in equilibrium**.

But even the highly liquid markets like forex don't have a **constant, stable liquidity**.

While some price levels will concentrate a **high activity of the market participants**, some levels can have a **lack of interest**.

The areas on a price chart, where the **trading orders** and the **market activity concentrate**, will be called **liquidity zones**.

Of course, we will discuss how to recognize these areas, but first, let's discuss why these zones are so important.

A strong bearish movement initiated then.

The occurrence of imbalance is one of the most accurate signals in trading Smart Money Concepts. Learn to recognize that and catch strong bullish and bearish movements.

Order Block

The ability to recognize the imbalance pattern will help you to spot a significant zone on a price chart - **the order block zone**.

Order block is one of the most **hyped** terms in Smart Money Concept.

The main problem of the order block, however, is that its definition and explanation are **different** and even **contradictory** in various sources.

In this chapter, I will share **my vision of order block**.

I will explain **what is order block** in trading, how to identify it and apply in Smart Money Concept trading.

What is Order Block

Order block is a certain **area** on a price chart where a **significant amount of market orders were executed**.

Such an event causes a sudden price **reversal** and a **local shift of the market sentiment**.

The execution of a big amount of orders **causes the imbalance** in a supply and demand.

Opening of a significant volume of **buying orders** makes **demand dramatically exceed supply**.

Such an imbalance is usually accompanied by a formation of a **bullish engulfing candle**.

Take a look at a price action on EURJPY pair.

The market was falling steadily and it was strongly bearish.

A test of a **significant liquidity zone** triggered a sudden **reversal** and a shift in the market sentiment. The pair formed a **bullish engulfing candle** and then started to grow rapidly.

While the execution of a significant volume of selling orders makes **supply dramatically exceed demand**.

It creates the imbalance on the market. Our accurate indicator of that, is a formation of a **bearish engulfing candle**.

Above, you can see that USDJPY was trading in a strong bullish trend.

Then, a liquidity zone was tested and the price suddenly formed a **bearish engulfing candle**.

Order Block Zone

Order block will be the area based on the **range** of **the last candle before the imbalance candle is formed.**

A bullish order block zone will be based on the range of a bearish candle, preceding the imbalance bullish engulfing candle

In the example on EURJPY, a bullish order block will be based on the range of the last bearish candle before the formation of a bullish imbalance.

A bearish order block zone will be based on the range of a bullish candle, preceding the imbalance bearish engulfing candle.

In the example on USDJPY, a bearish order block will be based on the range of the last bullish candle before the formation of a bearish imbalance.

How to Apply Order Block

Once the Order Block is confirmed by a formation of a high momentum candle, it will be applied as the **safe area to trade the market from**.

With a high probability, the price will **retest** the **order block** after some time, before initiating a strong directional movement.

That will give you a perfect **entry for the trade**.

In our example on EURJPY, after a formation of a bullish engulfing candle, the price quickly retested the order block before a bullish wave started.

In the example on USDJPY, after a formation of a bearish engulfing candle, the price retested the order block zone and a sharp bearish rally started then.

Why The Market Retests the Order Block

Smart money, the institutional traders, trade with huge trading volumes. They can not execute all their orders at once within the order block zone.

Smart money tend to **split** their positions into a **pull of small orders**. Part of them is executed after the first test of an order block zone, another part(s) is executed during the retest(s).

With such a strategy, Smart money are trying to **hide their presence** and **mitigate the impact costs**.

Even though the retest of an order block is a very frequent event, always remember that there is **no guarantee** that it will be retested.

In some cases, a bullish / bearish rally will continue without its retest.

I believe that my understanding of what is order block is the most compelling. It is based on a solid logic and such blocks provide very accurate opportunities with high reward potential for trading smart money concept.

Smart Money Concept Trading Strategy

As you learned market liquidity, structure mapping, imbalance, order block, liquidity sweep and liquidity run, you are ready to study a trading strategy that combines all these elements.

In this article, we will study a profitable Smart Money Concept trading strategy that works perfectly on any Forex pair, Gold, Silver or any other financial instrument

This strategy is based on 7 important steps:

1. Structure mapping and trend analysis
2. Liquidity zones analysis
3. Test of liquidity zone
4. Inducement
5. Imbalance
6. Order block
7. Trade execution

We will carefully go through every step of the strategy and study multiple real market examples.

Demand Zone Trading

The first step in our trading strategy will be the **analysis of a market trend** on a **daily time frame** with **structure mapping**.

Analyzing GBP/NZD on a daily time frame, we can see that the conditions for a bullish trend are met.

The second step will be to **find liquidity - supply and demand zones** on a **daily time frame**.

According to our rules, here are 3 liquidity zones that I spotted on GBP/NZD. We see 2 demand zones and 1 supply zone.

The third step will be to wait for a **test of a liquidity zone**.

And on that step, we should remember an important rule:

We will wait only for a test of a liquidity zone that **ALIGN** with the market trend.
It means that we will wait for a **test of a demand zone** in a **bullish trend**.

We will wait for a test of a **supply zone** in a **bearish trend**.

The only demand zones that meets these criteria on GBPNZD is Demand Zone 1.

It aligns with a bullish trend.

We don't consider Demand Zone 2, because a bearish violation of a Demand Zone 1 will be a Change of Character and a violation of a bearish trend.

And here is how a test of a liquidity zone should look like. The price should simply reach that.

After we identified a test of a significant liquidity zone that aligns with a market trend, we will start analyzing **lower time frames**.

We will look for a **liquidity grab**, **order block** and **imbalance** on **4H** and **1H** time frames.

Here is a **liquidity grab** that is confirmed by a **bullish imbalance**.

We see a false violation of a liquidity zone, followed by a high momentum bullish candle.

It will be our strong **bullish signal**.

In order to identify the **entry point**, the next step will be to identify the **order block zone**.

According to our rules, here is the order block zone on a 4H time frame.

Our **entry level** will be the level of the **upper boundary** of the **order block zone**.

Here is such a level on GBPNZD.

A buy limit order should be set on that level.

Please, note that in that particular case we don't need a 1H time frame analysis, because we have a confirmation signal on a 4H time frame. We will analyse an hourly time frame only when **THERE IS NO SIGNAL** on a 4H time frame.

Safe stop loss should be **below the lowest low** of a **bearish movement**.

To safely calculate a stop loss in pips for the trade, simply take 0.5 ATR - Average True Range.

For Average True Range indicator, take the **default settings - 14 length**.

Here is a safe stop loss level on GBPNZD. ATR is 55 pips. Our stop loss for the trade is 28 pips.

Take profit for the trade will be based on the **closest 4H liquidity - supply zone**.

That is the closest supply zone that I spotted on GBPNZD on a 4H time frame.

Your target level should be a couple of pips **below** a **supply zone**.

That is a perfect target level.

Look how perfectly the market reached the target!

As you can see, that trading strategy is quite complex and combines different important elements. But what I like about this SMC trading strategy is that it truly makes sense.

The intentions of Smart Money are crystal clear here and the trade execution rules are straight forward.

Supply Zone Trading

Now, let me share with you the in-depth example of trading Supply Zone with our SMC trading strategy.

Structure Mapping

Similarly to a previous example, our first task will be to execute a structure mapping on a **daily** time frame and identify the market trend.

Here is my structure mapping on EURCAD on a daily. We see that the pair is trading in a strong bearish trend on a daily.

Liquidity Zones

What we do next, we **analyze the liquidity zones**.

Here are 4 supply zones that I spotted.

We will trade only the liquidity zones that **align with a current bearish trend**.

It will be **Supply Zone 1 & 2.**

Test of Supply Zone

After that, we wait for a **test** of one of the supply zones that we spotted.

*Here is the exact moment of a **test** of a Supply Zone 1 on EURCAD.*

Liquidity Grab and Imbalance

Once we see a **test** of a supply zone, we start looking for a **liquidity grab** - the inducement and a trap with a consequent **bearish imbalance** on **4H/1H** time frames.

The price was coiling around that liquidity zone for many days before a confirmed liquidity grab with a consequent bearish imbalance occurred.

Order Block

To identify a **perfect entry** for shoring the pair, we should find the **order block zone** next.

Here is the order block zone on EURCAD.

Entry

A **safe entry** for a short trade is the level of a **lower boundary** of the **order block zone**.

Above, you can see that level on EURCAD.

Stop Loss

Stop loss should be **0.5 ATR** above the **highest high** of a bullish movement.

In our example, ATR is 32 pips. Our stop loss for the trade will be 16 pips above the high.

Target

Our target will be the **closest demand zone** on a 4H time frame.

Here is such a demand zone on EURCAD.

Take profit level should be a **couple of pips** above that.

That is the best take profit level for EURCAD.

That is a beautiful trade.

Expectations, Recommendations, Tips

The trading strategy that I shared with you works perfectly on major and minor Forex pairs, Gold, Silver, Oil, Indexes and Crypto.

Being applied properly, it should have around **65% winning rate**.

Planning the trade, make sure that you always have a **positive reward to risk ratio**. It should be at least **1.2/1**.

If the trading setup provides worse ratio, **do not take a trade**.

Always pay attention to **economic calendar**.

Stick to a simple rule: **do not trade 2 hours ahead of High Impact News** in the economic calendar.

If you have an active trading position, and you see High Impact News coming, move your **stop loss to entry 10/15 minutes ahead** of the release of the news.

You can apply this SMC trading strategy for **scalping** as well.

You should simply change the combination of time frames.

Execute structure mapping, liquidity and trend analysis on a **4H time frame**.

Look for a confirmation and entry on **30 and 15 minutes** time frames.

Thank You For Reading

I hope that you enjoyed this book. I tried to make it simple and sophisticated simultaneously, so it could be useful both for experienced and newbie traders.

Once you complete the book, do not rush trading on a real account.

Spend at least 2 months on a demo account and if you see a positive result at the end of the period, only then switch to real trading.

Do back testing, try to apply the rules and techniques that we discussed for making predictions on different financial markets.

Track your results, be patient and good luck in your trading journey.
